

Lab1 Conservation of mass/energy E = mc² or Einstein 's big idea

Part1: watch the movie *Antoine Lavoisier and the conservation of mass* from PBS/Nova and *Lisa Meitner and the fission of the atom*

<http://www.youtube.com/watch?v=SQJJYoYvbvk>

Antoine Lavoisier built an experiment that shows the conservation of mass and produces hydrogen gas H₂:

In his experiment, iron is mixed with water vapor to produce H₂ and iron oxyde.

What is the other name for iron oxyde ? _____

Lavoisier carefully showed that mass of reactants = mass of products.

He also showed that you can produce water H₂O by mixing hydrogen H₂ and _____.

The same principle is used in a hydrogen fuel. You get energy by combining H₂ and O₂ because the binding energy involved in H₂O is less than in H₂ and O₂. Why do you think people believe in a hydrogen economy ?

Hint: think waste product and energy independence. Compared to an economy based on oil.

He also used electricity (using a static electricity generator newly developed) to perform the opposite reaction:

energy (electric) + H₂ + O₂ = water.

How do you think we produce H₂ today ?

So why using hydrogen fuel is not very efficient ?

Why some people hated Lavoisier ?

What happen to him ?

(see <http://bastille-day.com/biography/Marat-Biography>)

Who was Jean Paul Marat.

Lavoisier is considered as the father of Modern Chemistry. He said:

rien de se cree, rien de se perd, tout se transforme. That means :

part2: introduction to Nuclear Physics

Mass/Energy is conserved during any chemical or nuclear reaction. During a nuclear reaction some of the mass involved can become pure energy in form of radiation like gamma rays. The transformation is described by a simple equation $E = mc^2$ where c is the speed of light ($3 \cdot 10^8$ m/s), E is the energy in

joules and m is the mass in kg.

In nuclear Physics elements noted are noted ${}^A_Z E$. A is the of nucleons (protons + neutrons). A is also called the mass number. Z is the number of protons or atomic number. Z is the ID of the elements. Carbon 12 and Carbon 14 are called carbon because they have 6 protons. So Z =6. So what is the difference between carbon 12 and its isotope carbon 14?

How many neutrons Carbon 14 has ? _____

Consider the radioactive decay of Uranium 238 = Thorium 234 + alpha particle (helium)/

Note that the number of protons (subscript number) is conserved (conservation of charge) as well as the number of nucleons (superscript number = neutrons+protons). This is the conservation of number. The decay is spontaneous because the binding between the constituents of the uranium is not as strong as in thorium and helium. In the process, uranium loses some mass to energy. The binding energy in elements increases with the number of nucleons up to iron then it decreases. The strong nuclear force is at work.

Radium 226 decays into radon 222 and an alpha particle. Use the periodic table to write this equation:

<http://www.ptable.com/>

Write the nuclear equation for the decay of uranium 234 into thorium 230 and an alpha particle.

Write the nuclear equation for the decay of radium 226 to radon 222 and an alpha particle

It is possible to shoot alpha particles at an element to cause a nuclear reaction. Rutherford bombarded nitrogen 14 with alpha and got a new element :

Find this new elements using the conservation of mass and the conservation of charges. (use the periodic table).

In 1932 Irene Curie (daughter of Marie) and her husband showed that beryllium 9 bombarded with alpha particles were emitting carbon 12 and a unknown particle:

What was this new particle ? (remember Z is for the charge) _____

Energy/mass is always conserved. For example When an electron collides with its “evil twin” the anti electron or positron they annihilate each other. Matter and anti matter annihilate and produce energy. The matter becomes pure energy = gamma rays.

Compute the energy of the gamma rays if the mass of electrons and anti electrons is $9.11 \cdot 10^{-31}$ kg
Use the formula $E = m c^2$ with m the total mass (electron + positron).

$$E = \text{_____ J}$$

convert the energy to eV (unit used in nuclear Physics). $1 \text{ eV} = 1.6 \cdot 10^{-19} \text{ J}$

$$E = \text{_____ eV} \quad \text{Then convert to MeV} \quad E = \text{_____ MeV} \quad (1 \text{ MeV} = 1,000,000 \text{ eV})$$

The mass of a proton is $1.67 \cdot 10^{-27}$ kg

Find the energy equivalent of the proton's mass in joules/ $E = \text{_____ J}$

convert this value to eV / $E = \text{_____ eV}$

Find the lowest energy of a gamma ray that could produce a proton-antiproton pair.

$$E = \text{_____ eV}$$

part3: problems = complete the nuclear equations

1)

2) A radioactive polonium isotope ${}^{214}_{84}\text{Po}$, undergoes alpha decay and becomes lead. Write the nuclear reaction.

3) Complete the nuclear equation:

4) alpha particles are bombarded at nitrogen:
